Causal Inference With Observational Data

└─Causal Model

Rubin Neyman Causal Model

1

Fundamental problem with program evaluation is that it is physically impossible to observe counterfactual

2

Rubin (1974) gave us the model of identification of causal effects, which relies on the notion of a **synthetic counterfactual** for each observation. The model is based on work by Neyman (1923,1935) and Fisher (1918,1925); see also Tukey (1954), Wold (1956), Cochran (1965), Pearl (2000), and Rosenbaum (2002).

Causal Inference With Observational Data

-Analytical Framework

Matching

- Basic idea of matching is to compare outcome of treated and untreated individuals with similar x's and then aggregating across x's to get population average treatment effect. Advantage to regression approach is that it does <u>not</u> assume x's linearly effect outcomes.
- **Propensity score matching (PSM)** $\Delta^{M} = \frac{1}{N_{T}} \sum_{i \in (D=1)} [y_{1,i} - \sum_{j} w(i,j)y_{0,j}] \text{ is to}$ estimate the propensity score from the data, and then use that estimate to weight treatment effects for each propensity score accordingly to arrive at average treatment effect.

Causal Inference With Observational Data

L_{Results}

Comparision of Groups: Before versus After Matching

1

Table: After Matching: Balanced Household Characteristics

| Variable | Treatment | (Untreated) |
|------------------------------|-----------|-------------|
| Pipewtr. in house? | 23.2% | 15% |
| Rural | 53% | 58% |
| Head Hd has sec. or more ed. | 45% | 41% |
| House $Floor = Cement$ | 30% | 33% |
| Richest Quintile | 52% | 52% |
